Cluster and area sampling

Cluster sampling and area sampling is mcq. Difference between cluster and area sampling. Differentiate between cluster and area sampling. What is cluster sampling. Distinguish between cluster and area sampling.

(Image: Sampling cluster) Definition: Cluster sampling studies a cluster of the relevant population. It is a project where the sampling unit consists of multiple cases such as a family, a classroom, a school or even a city or school system. Cluster sampling is also known as area sampling. Some authors consider it synonymous with multi-stage sampling. In multi-stage sampling, the cases to be studied are randomly collected in different stages. For example, in studying the problems of middle class workers in a state, the first step will be to collect some districts in the state. The next step will be to randomly collect some rural and urban areas for study. In the third phase, some families belonging to the middle class will be collected. The last step will be to select working couples from these families. Thus, the stages will be: (Cluster sampling method) (State â > Districts â > Middle class families â > Working couple in these families) The zone sampling or cluster sampling method is used when the population is concentrated over a large area and it is not possible to study the entire population at one stage. Each sampling method has its own merits and demerits. Below are some of the advantages and disadvantages of Cluster Sampling. Cluster sampling offers the following advantages: Cluster sampling is cheaper and faster. It is cheaper to look at clusters of units in a population than randomly selected units scattered throughout the state. The cluster sample allows any accumulation of large samples. The loss of precision per case is more than compensated by the ability to study larger samples for the same cost. Cluster sampling can combine the benefits of both random sampling and stratified sampling. The cluster sampling procedure allows information to be obtained from one or more areas. Demerits of Cluster Sampling The following are the disadvantages of Cluster Sampling: In a cluster sample, each cluster can be composed of units similar to each other. This can produce a large sampling error and reduce the representativeness of the sample. In Cluster Sampling, when an unequal size of some subsets is selected, a sample bias element will appear. This type of sampling cannot be applied to another area. Sometimes, an adequate number of cases from the stand point to increase the precision of the sample is not selected, an overlapping effect may occur. Cluster sampling is a sampling method in which populations are placed in separate groups. A random sample of these groups is then selected to represent a specific population. Yes of a process that is usually used for market research when there is no possible way to find information about a population or demographic as a whole. There are 3 requirements that must be met for cluster sampling to be an accurate form of information collection. Groups must bePossible heterogenes, containing distinct and different subpopulations within each cluster.ach group should offer a smaller representation of what the entire population or demographics takes place. Group must be mutually exclusive to each other to prevent data from overlapping. It should not be possible for two clusters to occur together. These requirements are met, there are two types of cluster sampling that can be executed. In stage cluster sampling, each element is used in each selected cluster. In two-stage cluster sampling, a randomized sampling technique is used for selected clusters to generate information. This is the key points to consider when examining the benefits and disadvantages of cluster sampling.List of the benefits of cluster sampling1. It allows research to be conducted with a reduced economy. If you had to search for a specific demographic or community, the cost of interviewing each family or individual within the Group would be very limiting. Using cluster sampling, you can fill out information about certain demographic data or community by reducing the number required to generate accurate data. Although no data is 100% accurate without a complete search process of each person involved, cluster sampling gets results within a very low margin of error.2. Cluster sampling reduces variability. All forms of sampling create estimates. What cluster sampling provides is a more accurate estimation process when clusters were put together appropriately. Supposing each cluster is representative of the general population that is studied, the information obtained through this method offered a reduced variability in its results because it is a more accurate reflection of the Group as a whole.3. It is a more feasible approach. The ability to manage large data inputs which would be obliged by a complete demographic or community sampling would not be feasible for the average researcher. The design of the cluster sampling approach is specifically designed to take into account large populations. If you need to find representative data of a large group, the cluster sampling allows you to extract information collected in a usable format.4. Cluster sampling can be taken from multiple areas. Cluster can be defined within a single community, multiple or more demographic communities. The procedures used to obtain information follow the same process, no matter how big the sample is. This means that researchers can generate usable information on a neighborhood using a random sample of certainThey can also discover large-scale information by approaching demographic data in different areas to generate national level results.5. It offers the benefits of random sampling and layered sampling. What is illustrated the sampling of the cluster is the fact that it includes all the advantages of randomized and layered stratified samplingin his processes. This helps reduce the potential of human prejudice within the information collected. The information assembly process is also simplified, reducing the risks of negative influences caused by random variations. When combined, the results obtained from the sample can generate conclusions that can then be applied to the larger population.6. Cluster sampling creates large data samples. It is much easier to create larger samples of data using cluster samples due to its structure. Once clusters have been designed and entered, the information collected is similar to each cluster. This makes it possible to compare data points, find conclusions within specific population groups, and generate monitoring information that can look at how different clusters evolve over time. List of Disadvantages of Cluster Sampling1. It is easier to create biased data within the cluster sampling. the integrity of the conclusions that you can find. When creating a cluster, however, each demographic, community or population group will have a certain level of overlap on an individual level. This creates a level of variability within data that creates sampling errors on abase. In some cases, the sampling error could be sufficiently broad to reduce data representation, disabling conclusions.5. It requires equality of size to be effective. One of the main disadvantages of the cluster sampling is that it requires equality of size to lead to accurate conclusions. If a cluster has a representative sample of 2,000 people, while the second cluster has 1,000 and all the other 500, then the first two clusters will be subrepresented in the conclusions, while the smaller clusters will be overrepresented. This process can lead to a disparity of data, which creates a large sampling error that can be difficult to identify.6. Cluster sampling results only apply to those population groups. The problem that arises with the cluster sampling is the fact that the populations they contain are representative only of that specific group. If the cities of North Carolina were examined, for example, information obtained from such research could not be accurately applied to the general population of the United States. It would be accurate only for the state population, and even in this case, it may not be possible to apply results based on regional differences. That's why there must be strong definitions on the spot for each cluster so that the search is accurate.7. Requires a minimum number of cases for accuracy. Cluster sampling requires more research points to reduce sampling errors that research produces. Without a high level of research, it increases the potential for overlaying data. There is also a greater risk of obtaining unilateral data through this process if you take fewer examples from each cluster.8. The sampling cluster only works well when people can be classified as units. The processes involved in cluster sampling require people to be classified as units instead of individuals. This would mean identifying them with a specific group, such as the 'Republicans' or the 'Democrats'. If you have to collect individual data points, then you need a different type of search. These benefits and disadvantages of cluster sampling can help us find specific information about a large population without the time or cost investment of other sampling methods. At the same time, in the absence of rigorous controls and strong skills of researchers, there may be more errors in information that can lead researchers to false results. For this reason, only experienced researchers who are familiar with area sampling should regularly use this type of research.
