## Retinal tear floaters

What is a retinal tear? The retina is a layer of nervous fabric that lines inside your eye. It consists of light sensitive cells that send signals to your brain and allow you to see. The retina is very thin, and a tear in it is a very serious and potentially blinding problem. If a retinal tear is developed, it can allow the fluid to enter the retina and cause a retinal detachment. The common symptoms of a retinal tear include the feeling of light flashes in the eyes and floater. Sometimes a retinal tear can be associated with bleeding in the eye that leads to hundreds of new floats and / or a loss in vision if the blood fills the eye. \* Courtesy image of the National Eye Institute Why do I have a retinal tear? Our eye is full of a substance similar to a gel called vitreous. As we age this gel breaks and becomes more liquefied. In the end, usually after 60 years, this liquefaction process sets the gel from the back of the eye. This event is called a rear vitreous detachment (or PVD). A PVD is completely normal and eventually happens to everyone; However, it is also the moment when most eyes have the highest risk of developing a retinal tear. This is because the vitreous gel becomes more mobile and the gel can pull and open a tear in a retina area where it is more adherent to it. There are several risk factors that put some people at a higher risk for the development of a retinal tear. These include: A € à,~ à € Myopia (near view) A € à,~ à € Have areas of thinning in the retina (lattice degeneration) A € à,~ à € having had cataracts or another intercular intervention A € à,~ à € having a story of trauma at the eye A € à,~ à € having a history of a retinal tear or detachment in the viewmate A € à,~ À € to have family with a story of tears or Retina detachment, what are the floaters? Floaters are small groups of cells or fabrics that are formed in the vitreous gel, the clear substance similar to gelatin that fills the internal cavity of the eye. The appearance of these small points, circles, lines or cobwebs can cause a lot of concern, especially if they suddenly develop; However, they usually reflect a normal aging process for most people. As a day, the vitreous gel tends to liquefy. Although the small floaters can be seen at any, larger and more obvious that they suddenly appear tend to do so when the vitreous gel is liquee to the extent that its back surface starts to separate from the retina. This occurrence is called a rear vitreous detachment (PVD) and its probability increases with age. Incontio, Floaters are the result of inflammation within the eye or crystal deposits that form in the vitreous gel rather than in the PVD. What are Lempli? Retina stimulation produces flashes flashing. Light flashes often occur when the vitreous gel hooks or separates from the retina as or shortly after the PVD. Light flash phenomena can also originate from the visual centers of the brain seen with visual auras associated with migraine. Are they serious floater or flash? They can certainly be. During or after the PVD, the retina and / or a blood vessel can be torn, which causes bleeding in the eyes that can appear as a cloud of new floats or flashing. The tears in the retina are series and generally must be sealed to avoid a threatening retinal detachment of the vision. In the case of dense bleeding that is not erased quickly by itself, it is recommended to remove blood and allow blood treatment and allow the treatment of the underlying source of bleeding. Without examination by an ophthalmologist, there is no way A person to determine if floating or flash are serious in à €
